New York City Collision

By Kazi Siam, Ming Hin Cheung

Motivation

It was November 21, 2020, when I got a call from one of my friends who found himself in a car accident. I rushed to the scene and witnessed one of the hideous accidents I have ever seen. His friend was driving the car, and my friend was in the passenger seat. They were driving at 97-mph in a 25-mph limit. They were both intoxicated. They plowed into a 52-year-old man who was driving his car through a green light at the intersection. Fortunately, nothing happened to my friend. However, that 52-year-old man was pronounced dead at the scene. My friend's friend was charged with vehicular manslaughter. This is just one of the many vehicular accidents that take place in New York City.

According to the New York State Department of Health, there were 228,047 car accidents in all of New York City in 2018. That's about 19,000 car accidents per month, 4,750 car accidents per week, 678 car accidents per day, 28 car accidents per hour, or one-car accident every 2 minutes.

NYPD keeps track of all the motor vehicle collisions that happen in New York City. In our project, we will analyze one of the popular datasets in NYC Open Data called Motor Vehicle Collisions. Through our analysis, we will see which months and/or years most car accidents happen. We will also see which borough has more car accidents. We will also build a model that can predict in which borough the accident will happen based on the information about the accident.

It is interesting because people should be careful when driving a car. It only takes one moment of negligence to change someone's life forever.

Data

We are getting the dataset from NYC Open data. We're choosing it because it's one of the largest and most well-used open data platforms in the world for public use. There are multiple ways to access the dataset, such as CSV, Excel Spreadsheets, and API Endpoint. There are limitations on the data, there're many empty fields/missing data in our dataset, therefore, we need to do data cleaning.

Data Cleaning

The first step we had to do before building our model is to clean the data.

We exported the Motor Vehicle Collisions crash dataset from NYC Open Data.

```
In [3]: df.head()
```

Out[3]:

	CRASH DATE	CRASH TIME	BOROUGH	ZIP CODE	LATITUDE	LONGITUDE	LOCATION	ON STREET NAME	CROSS STREET NAME	OFF STREET NAME	...	CONTRIBUTING FACTOR VEHICLE 2	C
0	04/14/2021	5:32	NaN	NaN	NaN	NaN	NaN	BRONX WHITESTONE BRIDGE	NaN	NaN	...	Unspecified	
1	04/13/2021	21:35	BROOKLYN	11217.0	40.68358	-73.97617	(40.68358, -73.97617)	NaN	NaN	620 ATLANTIC AVENUE	...	NaN	
2	04/15/2021	16:15	NaN	NaN	NaN	NaN	NaN	HUTCHINSON RIVER PARKWAY	NaN	NaN	...	NaN	
3	04/13/2021	16:00	BROOKLYN	11222.0	NaN	NaN	NaN	VANDERVORT AVENUE	ANTHONY STREET	NaN	...	Unspecified	
4	04/12/2021	8:25	NaN	NaN	0.00000	0.00000	(0.0, 0.0)	EDSON AVENUE	NaN	NaN	...	Unspecified	

5 rows × 29 columns

Fig. The first 5 rows in the row dataset

The Motor Vehicle Collisions data contains information from all police reported motor vehicle collisions in NYC. It has about 600,000 rows and 29 columns. Each row represents a crash event.

Because the dataset size is too huge, we're going to take 50,000 random samples from it to ease our process and to make it efficient for this task.

Also, there are several features that we don't need for our problem. We're using the Python Pandas Data Frame library to clean our dataset.

#	Column	Dtype
0	CRASH DATE	object
1	CRASH TIME	object
2	BOROUGH	object
3	ZIP CODE	object
4	LATITUDE	float64
5	LONGITUDE	float64
6	LOCATION	object

Fig. Checking Column names in the raw dataset

Hence, we must drop those features since they will be having no effect on our output. For example, we dropped the columns, Zip Code, on street name, cross street name, vehicle code… because these columns aren't relevant to our problem, which is predicting which borough this accident happened.

```
#Checking for missing values
df.isnull().sum()
```

```
CRASH DATE                          0
CRASH TIME                          0
BOROUGH                         15218
ZIP CODE                        15220
LATITUDE                         5809
LONGITUDE                        5809
LOCATION                         5809
ON STREET NAME                  10200
CROSS STREET NAME               17831

VEHICLE TYPE CODE 5             49827
```

Fig: Checking for missing values.

Then, it comes to the part of dealing with the missing values. Since some of the features contain a lot of missing values (including our target feature), we will have to fix them. Starting from our target feature, since it is a categorical feature and our dataset is huge, we're simply going to drop missing values in our target variable.

```
Mean of Latitude:  40.67402280233771
Median of Latitude:  40.71886135

Since both the values are approx. same, it means there are no outliers in latitude & longitude.
```

Fig. Finding outliers

We also checked the latitude and longitude to confirm there are no outliers in the dataset, meaning that the location is indeed in NYC,
After that, we're going to compute missing values for the test of our features. Since our data contains no outliers at all, we filled all the missing values using the mean strategy.

```
#Checking again for missing values
df.isnull().sum()
```

```
CRASH DATE                      0
CRASH TIME                      0
BOROUGH                         0
LATITUDE                        0
LONGITUDE                       0
NUMBER OF PERSONS INJURED       0
NUMBER OF PERSONS KILLED        0
NUMBER OF PEDESTRIANS INJURED   0
NUMBER OF PEDESTRIANS KILLED    0
NUMBER OF CYCLIST INJURED       0
NUMBER OF CYCLIST KILLED        0
NUMBER OF MOTORIST INJURED      0
NUMBER OF MOTORIST KILLED       0
```

Fig. Checking missing values

We confirmed there are no missing values after fixing it. Finally, we fixed the datatype of each column.

Exploratory Data Analysis

After cleaning our data, we made an EDA, which analyzes the cleaned dataset, and discovers the patterns, relationships within our dataset. We created data visualizations to help us build our model in predicting which borough did this accident happen in based on given information.

First, we made a heatmap to show the correlation of numerical features in our data.

Fig. Heatmap on features correlation

- The Number closer to zero indicates a lower correlation (precise 0 implying no significant relation).
- The Number around +1 to one indicates a more positive correlation.
- The Number around -1 implies a more negative correlation.

A heatmap is a graphical representation where individual values of a matrix are represented as colors. A heatmap is especially useful in visualizing the concentration of values between two dimensions of a matrix. This helps in finding patterns and gives a perspective of depth.

We found out that the number of motorists injured has a strong correlation with the total number of persons injured with a 0.89, meaning that in an accident, motorists are mostly the ones who are injured if it’s involved, instead of others (pedestrians, cyclists).

We also found out that the number of people killed has a strong correlation with the number of pedestrians killed, meaning that pedestrians are the ones that have a higher death rate than drivers in an accident.

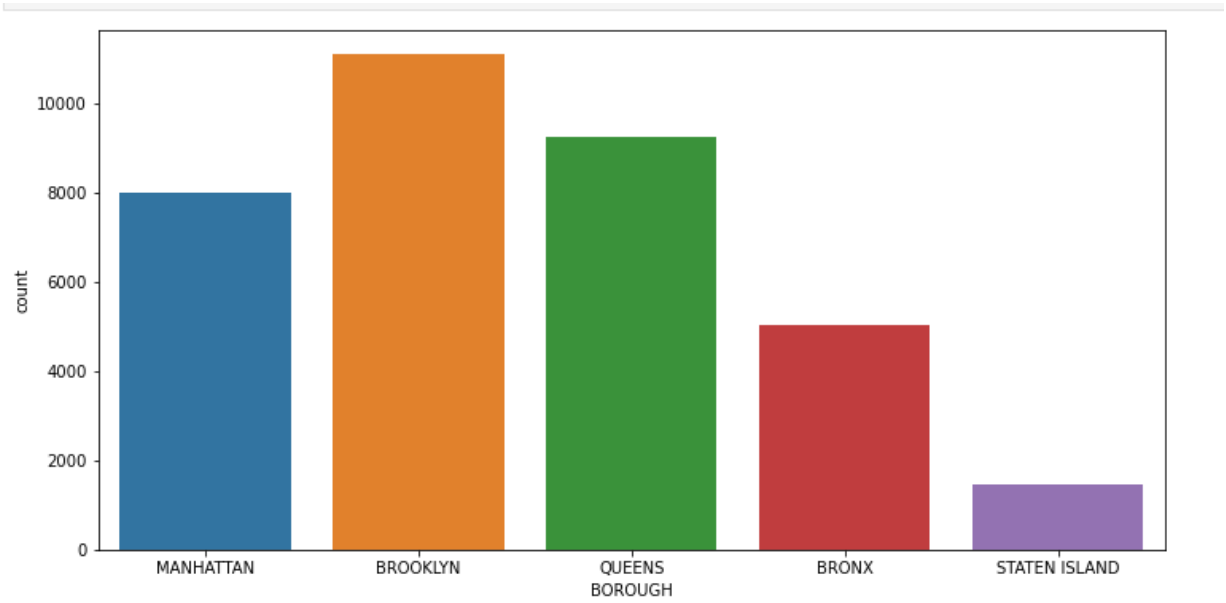

Fig. The number of vehicular collisions in boroughs

Brooklyn and Queens had the greatest number of collisions, and State Island had the least.

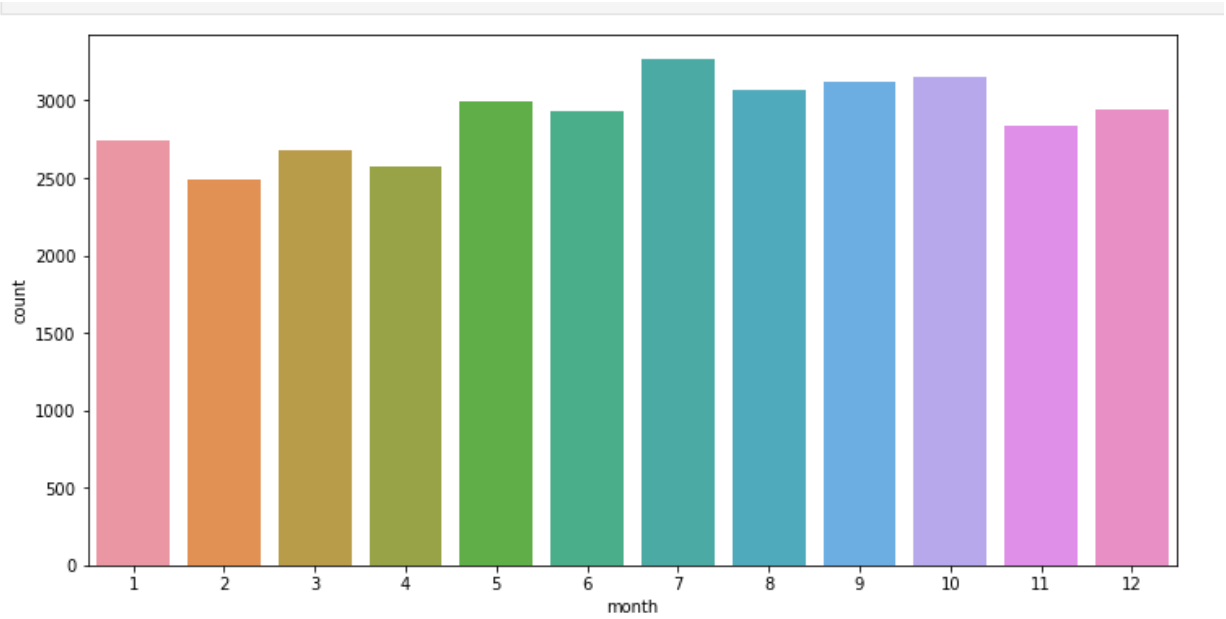

Fig. The number of collisions by a month bar chart

As we can see here, the greatest number of collisions occurred in July overall which is numbered as 7 in the bar chart.

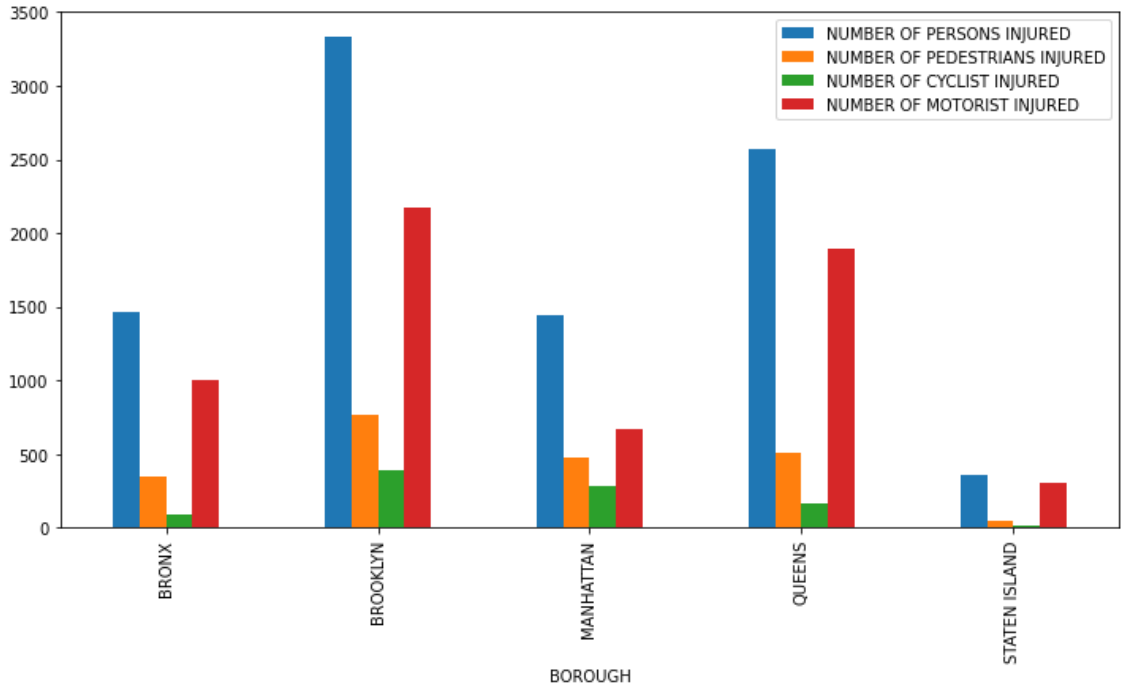

Fig. Boroughs with number of injuries

The above visualizations tell us that Brooklyn and Queens have the highest total number of injuries, in contrast to the lowest, Staten Island.

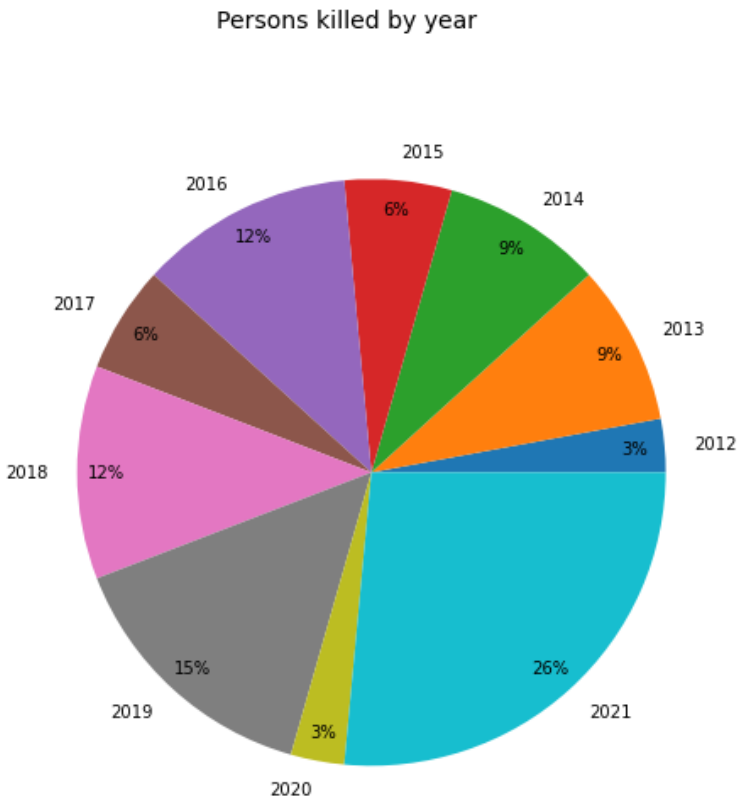

Fig. Pie chart for people killed by year

From the above pie chart, we can see that the highest percentage of deaths occurred in 2021. Surprisingly, it's this year, but the year hasn't ended yet.

Model

We built a logistic regression model for our project because logistic regression can predict a data value based on prior observations of a data set, which is exactly what we want to answer our data science question. "In which borough did this accident happen?"

Evaluation

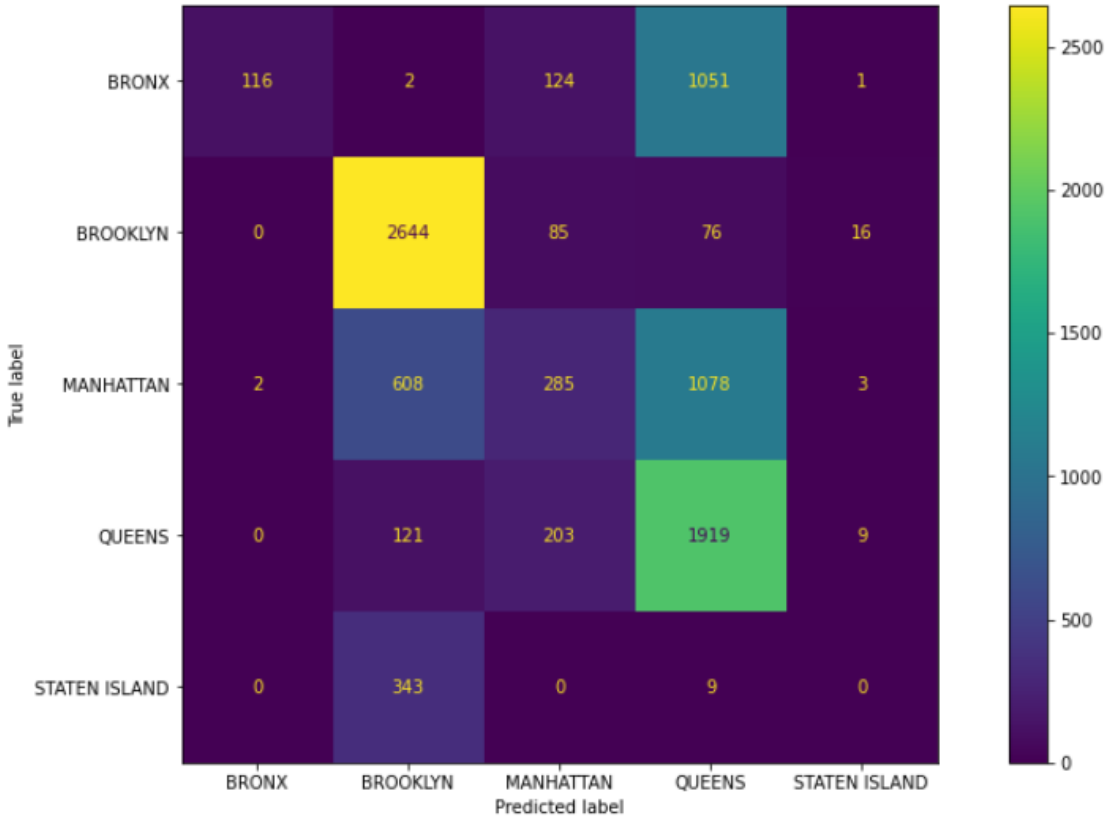

Fig. Confusion Matrix on evaluation our model

We used a confusion Matrix to evaluate our model. It's a performance measurement for machine learning classification problems where output can be two or more classes. It is a table with different combinations of predicted and actual values,
measuring a confusion matrix provides better insight in particular on our mode.

Here’s an example to help you better understand the matrix, on the first column on the confusion matrix our model predicts 378 accidents are from the Bronx, and we correctly predicted that 372 accidents are from the Bronx, but we falsely predicted that 3 accidents are from Manhattan and 3 accidents are from queens. For Brooklyn, we correctly predicted 2385 accidents were from Brooklyn, but falsely predicted 2 from Brox, 608 from Manhattan, 121 from Queens, and 343 from Brooklyn. This shows that we can further improve our models.

	precision	recall	f1-score	support
BRONX	0.98	0.30	0.46	1245
BROOKLYN	0.68	0.89	0.77	2682
MANHATTAN	0.30	0.09	0.14	2020
QUEENS	0.49	0.87	0.63	2349
STATEN ISLAND	0.00	0.00	0.00	368
accuracy			0.58	8664
macro avg	0.49	0.43	0.40	8664
weighted avg	0.55	0.58	0.51	8664

Fig, Classification report of our model

Precision

Precision shows us that from all the classes we have predicted as positive, how many are actually positive. Precision should be as high as possible.

F1- score

F-score helps to measure Recall and Precision at the same time. It uses Harmonic Mean in place of Arithmetic Mean by punishing the extreme values more.

Recall

Recall tells us that, from all the positive classes, how many we predicted correctly. from all the positive classes, how many we predicted correctly.

Support

Support is the number of samples in data for that variable, the performance measures are better when the support is higher.

Future Work

- Describe what work you would do in the future. This can include work to improve your model, building-related models, and/or sourcing different datasets. Are there any other interesting questions you uncovered while you were working on your model?
